Birthday paradox

Fermat's method

- Integers modulo  $n$ : set of residue classes mod  $n$ :

$$\mathbb{Z}/n\mathbb{Z} = \{[r]_n : r \in \mathbb{Z}\}.$$

- How to do arithmetic in mod  $n$ ? What is  $[3]_4 + [1]_4$ ?

## Definition

Let  $n \in \mathbb{Z}^+$  and  $a, b \in \mathbb{Z}$ . Then,

$$[a]_n + [b]_n = [a + b]_n$$

$$[a]_n \times [b]_n = [a \times b]_n$$

- Similarly,

$$[a]_n - [b]_n = [a]_n + [-b]_n = [a - b]_n.$$

Cycles in  $\mathbb{Z}/n\mathbb{Z}$

Floyd's cycle-finding

Pollard's  $\rho$

Birthday paradox

Fermat's method

- $\gcd(a, b)$  is the greatest common divisor of  $a$  and  $b$
- $a, b$  are called coprime or relatively prime if  $\gcd(a, b) = 1$ .  
 $a$  is called a totative of  $b$  and vice versa.
- Bézout's identity: If  $\gcd(n, m) = d$ , then there exist  $k, l$  s.t.  $nk + ml = d$ .
- $\varphi(n)$  counts the number totatives less than  $n$ :

$$\varphi(n) = |\{c : 1 \leq c < n \text{ and } \gcd(c, n) = 1\}|.$$

- We have  $\varphi(mn) = \varphi(n)\varphi(m)$ .

Trial Division

Pollard's  $p-1$

Cycles in  $\mathbb{Z}/n\mathbb{Z}$

Floyd's cycle-finding

Pollard's  $\rho$

Birthday paradox

Fermat's method

- Notice: no division in mod  $n$ !
- Division is usually defined as multiplication by the multiplicative inverse.
- Multiplicative inverse of  $[a]_n$  is  $[b]_n$  such that  $[a]_n[b]_n = [1]_n$ ; i.e.  $ab \equiv 1 \pmod{n}$ .

## Theorem

$[a]_n \in \mathbb{Z}/n\mathbb{Z}$  has a multiplicative inverse if and only if  $\gcd(a, n) = 1$ .

- Drawing from previous example:  $\gcd(4, 2) = 2$ , while  $\gcd(4, 7) = 1$ .
- That means that every element except 0 in  $\mathbb{Z}/p\mathbb{Z}$  has an inverse, since a prime is coprime to every element below it.
- Bézout's identity again:  $\gcd(m, n) = 1$ , then  $m[m^{-1}]_n + n[n^{-1}]_m = 1$ .

Fermat's method

## Convention

We will denote the cost of multiplication by  $M(n)$  and the cost of the GCD by  $G(n)$  for  $n$ -digit numbers.

- Schoolbook multiplication:  $M(n) \in O(n^2)$ .
- Schönhage-Strassen:  $M(n) \in O(n \lg n \lg \lg n)$ .
- Euclidean GCD:  $G(n) \in O(n^2)$ .
- Schönhage's GCD:  $G(n) \in O(M(n) \lg n)$ .
- Modular exponentiation ( $a^k \bmod b$ ):  $O(M(c) \lg k)$ , where  $c = \max(\lg a, \lg b)$ .

## Theorem (Fundamental Theorem of Arithmetic)

*Let  $n$  be an integer. Then there exist unique primes  $p_1, p_2, \dots, p_k$  not necessarily distinct such that*

$$n = p_1 \times p_2 \times \dots \times p_k.$$

- In essence, every integer can be factored uniquely into primes. For example,  $20 = 2 \times 2 \times 5$ .
- FTA guarantees existence of that factorization, but how do you find it?

## Convention

In the following slides, every big O is given in terms of input **values** instead of input length.

## Corollary (Fermat's little theorem)

For  $a < p$ ,  $a^{p-1} \equiv 1 \pmod{p}$ . That is,  $p \mid (a^{p-1} - 1)$ .

- Assume  $p$  is a prime divisor of  $n$ .
- That means that  $\gcd(a^{p-1} - 1, n) \geq p$ .
- The preceding also works if the exponent is a multiple of some  $p - 1$ , i.e.  $a^K - 1$  where  $K$  is a multiple of  $p - 1$ .
- Goal: choose  $K$  such that it is likely to be the multiple of some  $p - 1$  for a prime divisor  $p$ .

Pollard's  $p - 1$ : Analysis

## Definition

*A sequence  $\{X_i\}_{i \geq 0}$  is considered periodic if there exists  $a$  such that  $X_{m+a} = X_m$  for all  $m \geq 0$*

- Ultimately periodic if for all  $m \geq M$  (some starting value)

- Let  $f : \mathbb{Z}/n\mathbb{Z} \rightarrow \mathbb{Z}/n\mathbb{Z}$ .
- Consider a sequence  $\{X_i\}_{i \geq 0}$  where  $X_i \in \mathbb{Z}/n\mathbb{Z}$  and  $X_{m+1} = f(X_m)$ .
- The sequence is ultimately periodic.

*Proof:*

- Assume  $X_0, X_1, \dots, X_{m-1}$  distinct for some  $m$  and  $X_m$  is not.  $m \leq n$  by Pidgeonhole
- Then,  $X_m = X_\mu$  for some  $0 \leq \mu \leq m-1$ .
- Let  $\lambda = m - \mu$  (period)
- By induction, we need to show that  $X_{n+\lambda} = X_n$  for all  $n \geq \mu$ .

**Pollard's  $\rho$**

Birthday paradox

Fermat's method

- Let  $p|n$  prime.
- Want  $p|(x - y)$  so that  $\gcd(|x - y|, n) \geq p$ .
- $p|(x - y)$  means  $x \equiv y \pmod{p}$ .
- When a cycle mod  $p$  is found, we find a factor.
- When does that happen? Birthday paradox
- For the birthday paradox to work, we need to expect that  $f$  is a uniform function: Every remainder has an equal probability of being chosen.
- This is a conjecture, but empirical data approximately supports it

Floyd's cycle-finding

Pollard's  $\rho$

**Birthday paradox**

Fermat's method

- “How many people need to be in a room so that there is a probability of  $m$  that two of them have the same birthday?”
- “How many random variables do we need to draw from  $f$  such that two of them have the same remainder mod  $p$  with probability  $m$ ?” ( $X_i \equiv X_j \pmod{p}$ )
- Of course,  $0 < m < 1$ .
- Original birthday paradox:  $m = 0.5$

Assume every event equally likely.

$$P(X_i \equiv r) = \frac{1}{p}$$

Assume the events are independent.

$$P(X_i \equiv r \text{ and } X_j \equiv r) = P(X_i \equiv r)P(X_j \equiv r) = \frac{1}{p^2}$$

Probability that once  $X_i$  is chosen,  $X_j$  will have same birthday:

$$P(X_i \equiv X_j) = \frac{1}{p}$$

Complement: probability that all remainders are different.

Let  $A_i$  be the event that  $X_i \neq X_j$  for all  $0 \leq j < i$ .

Then, the event that choosing  $\lambda$  random variables yields distinct remainders is

$$B_\lambda = \bigcap_{i=0}^{\lambda-1} A_i = B_{\lambda-1} \cap A_{\lambda-1}$$

By defn of conditional probability:

$$P(B_\lambda) = P(B_{\lambda-1})P(A_{\lambda-1}|B_{\lambda-1})$$

Then,

$$P(A_i|B_i) = \frac{p-i}{p},$$

since for  $A_i$ ,  $i$  remainders are already “occupied” and  $p-i$  remainders are “left.”

Expanding, we have (since  $P(B_1) = P(A_0) = 1$ )

$$\begin{aligned} P(B_\lambda) &= \prod_{i=0}^{\lambda-1} P(A_i|B_i) = \prod_{i=0}^{\lambda-1} \frac{p-i}{p} \\ &= \prod_{i=0}^{\lambda-1} \left(1 - \frac{i}{p}\right) = \frac{p!}{(p-\lambda)!p^\lambda} \end{aligned}$$

Using the approximation  $1 - x \approx e^{-x}$  (Taylor series),

$$P(B_\lambda) \approx 1 \times \prod_{i=1}^{\lambda-1} e^{-i/p} = e^{-\sum_{i=1}^{\lambda-1} i/p} = e^{-(\lambda^2-\lambda)/2p}$$

Now, we want  $P(B_\lambda) \leq 1 - m$ .

Notice that this gets us the median for  $m = 0.5!$

Thus,

$$e^{-(\lambda^2 - \lambda)/2p} \leq 1 - m$$
$$\lambda^2 - \lambda + 2p \ln(1 - m) \geq 0$$

Then,

$$\lambda \geq \frac{1}{2} + \frac{1}{2} \sqrt{1 - 8p \ln(1 - m)}$$

- Then, in Pollard's  $\rho$ , we find a cycle mod  $p$  with probability  $\frac{1}{2}$  after approximately  $\frac{1}{2} \sqrt{8 \ln(2)p} \approx 1.177 \sqrt{p}$  iterations.
- In fact, we always find a cycle mod  $p$  in  $\theta(\sqrt{p})$  steps.

Different analysis due to Knuth: mean instead of median.

$$E[\lambda] = \sum_{\lambda=1}^{p+1} P(B_\lambda) = 1 + \sum_{\lambda=1}^p P(B_\lambda) = 1 + \sum_{\lambda=1}^p \frac{p!}{(p-\lambda)!p^\lambda}$$

Define the Ramanujan Q function:

$$Q(n) = \sum_{k=1}^n \frac{n!}{(n-k)!n^k}$$

Then,

$$E[\lambda] = 1 + Q(p)$$

The Q function can be approximated by

$$Q(p) \approx \sqrt{\frac{\pi p}{2}} \approx 1.2533\sqrt{p}$$

Birthday paradox

Fermat's method

 $n$  must be odd.1: FERMAT( $n$ )2:  $a \leftarrow \lceil \sqrt{n} \rceil$ 3:  $b \leftarrow a^2 - n$ 4: **while**  $b$  is not a square **do**5:  $a \leftarrow a + 1$ 6:  $b \leftarrow a^2 - n$ 7: **return**  $a - \sqrt{b}$  $\triangleright$  or  $a + \sqrt{b}$

# Fermat's: Why does it work?

Overview

Modular  
Arithmetic

Division Algorithm  
and Congruence

Residue classes mod  
 $n$

Integers modulo  $n$

Arithmetic with  
integers mod  $n$

GCD and Totatives

Inverses mod  $n$

Euler's Theorem

Cost of  
Multiplication  
and GCD

Integer  
Factorization

Trial Division

Pollard's  $p-1$

Cycles in  $\mathbb{Z}/n\mathbb{Z}$

Floyd's cycle-finding

Pollard's  $\rho$

Birthday paradox

Fermat's method

- Every odd integer is the difference of two squares
- $n = a^2 - b^2 = (a + b)(a - b)$
- We hope that  $1 < a + b < n$  (or equivalently same for  $a - b$ )
- Rearrange:  $b^2 = a^2 - n$ .
- Try values for  $a$  until  $b^2$  is a square.
- Worst case:  $n$  is prime.  $O(n)$  steps.
- Works best when prime factor is close to square-root of  $n$ .

Birthday paradox

Fermat's method

- Is there a way to know when values of  $a$  make  $b^2$  a square?
- Bézout's identity again:  $\gcd(m, n) = 1$ , then
$$m[m^{-1}]_n + n[n^{-1}]_m = 1.$$

## Theorem (Chinese Remainder Theorem)

*Let  $\gcd(n, m) = 1$ . Then the following system has a solution and every solution is congruent mod  $mn$ :*

$$x \equiv a \pmod{n} \quad x \equiv b \pmod{m}$$

Solutions are  $x \equiv am[m^{-1}]_n + bn[n^{-1}]_m \pmod{mn}$ .
